Material available at:

[https://github.com/mfasiolo/workshop\\_BOZEN19](https://github.com/mfasiolo/workshop_BOZEN19)

These slides cover:

- 1 Intro to quantile GAM models
- 2 Fitting QGAMs
- 3 Quantile GAM modelling with qgam

# What is quantile regression

Regression setting:

- $y$  is our response or dependent variable
- $\mathbf{x}$  is a vector of covariates or independent variables

In **distributional regression** we want a good model for  $p(y|\mathbf{x})$ .

Model is  $p_m\{y|\theta_1(\mathbf{x}), \dots, \theta_q(\mathbf{x})\}$ , where  $\theta_1(\mathbf{x}), \dots, \theta_q(\mathbf{x})$  are parameters.

# What is quantile regression

Lots of options for  $p_m(y|\mathbf{x})$ : binomial, gamma, Poisson, Tweedie...

We consider continuous (not discrete)  $y$ .

Define  $F(y|\mathbf{x}) = \text{Prob}(Y \leq y|\mathbf{x})$ .

The  $\tau$ -th ( $\tau \in (0, 1)$ ) quantile is  $\mu_\tau(\mathbf{x}) = F^{-1}(\tau|\mathbf{x})$ .

# What is quantile regression

Given  $p_m(y|\mathbf{x})$  we can get the conditional quantiles  $\mu_\tau(\mathbf{x})$ .

# What is quantile regression

Quantile regression estimates conditional quantiles  $\mu_\tau(\mathbf{x})$  directly.

No model for  $p(y|\mathbf{x})$ .

# When is quantile regression useful

## No assumptions on $p(y|x)$ :

- no need to find good model for  $p(y|x)$ ;
- no need to find normalizing transformations (e.g. Box-Cox);

# When is quantile regression useful

Median income is a better indicator of how the “average” person is doing, relative to mean income.

# When is quantile regression useful

The median is also more **resistant to outliers**.

# When is quantile regression useful

## Some quantiles are more important than others:

- electricity producers need to satisfy top electricity demand
- urban planners need estimates of extreme rainfall

# When is quantile regression useful

## Effect of explanatory variables may depend on quantile

# When is quantile regression useful

$$q_{\tau}(\text{Demand}) = f_1(\text{Temp}) + f_2(\text{TimeOfYear}) + f_3(\text{Trend}) + f_4(\text{Holiday}) + \dots$$

These slides cover:

- 1 Intro to quantile GAM models
- 2 Fitting QGAMs
- 3 Quantile GAM modelling with qgam

# Quantile GAM estimation

In parametric GAMs  $\mu_\tau(\mathbf{x}) = F^{-1}(\tau|\mathbf{x})$ .

**Key fact:**  $\mu_\tau(\mathbf{x})$  is the minimizer of

$$L(\mu|\mathbf{x}) = \mathbb{E}\{ \rho_\tau(y - \mu) | \mathbf{x} \},$$

where  $\rho_\tau$  is the “pinball” loss (Koenker, 2005):

In additive modelling context  $\mu_\tau(\mathbf{x}) = \sum_{j=1}^m f_j(\mathbf{x}) = \mu_\tau(\boldsymbol{\beta})$ .

# Quantile GAM estimation

**Problem:** how to perform Bayesian update  $p(\beta|y) \propto p(y|\beta)p(\beta)$ ?

A coherent approach is the Gibbs posterior (Bissiri et al., 2016)

$$p(\beta|y) \propto \underbrace{e^{-\frac{1}{\sigma}\rho_{\tau}\{y-\mu(\beta)\}}}_{\text{pseudo } p(y|\beta)} p(\beta),$$

where  $1/\sigma > 0$  is the “learning rate”.

Recall that  $p(\beta) = p(\beta|\gamma)$ , hence we need to:

- select learning rate  $1/\sigma$
- select smoothing parameters  $\gamma$
- estimate regression coefficients  $\beta$

# Technical challenges

$\sigma$  controls width of credible intervals:

# Selecting the learning rate

We select  $\sigma$  so that the model-based uncertainty estimates match the sampling uncertainty, that is  $\sigma$  minimizes

$$\text{CalibrLoss}(\sigma) = \int \text{Dist}\{\text{var}_m(\mathbf{x}), \text{var}_{\mathbb{P}}(\mathbf{x})\} p(\mathbf{x}) d\mathbf{x},$$

# Quantile GAM estimation

We use a hierarchical fitting framework:

- 1 Select  $\sigma$  to optimise coverage

$$\hat{\sigma} = \underset{\sigma}{\operatorname{argmin}} \operatorname{CalibrLoss}(\sigma).$$

- 2 For fixed  $\sigma$ , select  $\gamma$  to determine smoothness

$$\hat{\gamma} = \underset{\gamma}{\operatorname{argmax}} \operatorname{LAML}(\gamma)$$

where  $\operatorname{LAML}(\gamma) \approx p(y|\gamma) = \int p(y, \beta|\gamma) = \int p(y|\beta)p(\beta|\gamma)d\beta$ .

- 3 For fixed  $\gamma$  and  $\sigma$ , estimate  $\beta$

$$\hat{\beta} = \underset{\beta}{\operatorname{argmin}} \sum_i \rho_{\tau}\{y_i - \mu(\beta)\} + \operatorname{Pen}(\beta|\gamma).$$

# Quantile GAM estimation

`qgam` uses a modified loss which we call Extended log-F (ELF) loss.

This is smooth and convex and, as  $\lambda \rightarrow 0$ , we have recover pinball loss.

Since `qgam` 1.3.0,  $\lambda$  (`err` parameter) is selected automatically.

# Selecting the learning rate

## Motivation for using ELF:

pinball loss becomes very asymmetric on extreme quantiles.

# Smoothing the pinball loss

$\lambda$  (called `err` in `qgam`) selected to **balance variance and bias**.

These slides cover:

- 1 Intro to quantile GAM models
- 2 Fitting QGAMs
- 3 Quantile GAM modelling with qgam

# Demonstration in R

For more details on methodology, see:
